## OWNER'S HANDBOOK

**TECHNICAL & OPTICAL EQUIPMENT**  
(LONDON) LTD

Zenith House, The Hyde, Edgware Road, London NW9 6EE

Printed in England

# Introduction

This handbook is primarily written and illustrated around the latest SLR camera from the USSR – the Zenith EM. Though this camera boasts many advanced features over its predecessors, the Zenith E and its earlier meterless version the Zenith B, the basic instructions may be applied equally well to all models. Where any differences occur between models these have been noted, and inset illustrations provided, if necessary, in the appropriate section of the book. Though many hints and tips towards better photography have been included, this handbook should in no way be thought of as a comprehensive guide to general photographic techniques. There are numerous useful books of this type available and if you are just taking your first shaky steps in photography it would

certainly benefit you to consult your local library or bookshop.

Your Zenith camera is sturdily built and will work happily under widely varying conditions. Do remember, though, that it is a precision-built optical instrument and should therefore be handled carefully and protected from violent shocks, damp, dust and sand and sudden changes of temperature. Take care of your camera and it will give you years of reliable service and brilliant pictures. The wide range of accessories available, particularly those from the USSR which offer outstanding value-for-money, enable you to cope with almost any photographic situation. You can build up as complete a system as you need at your own pace.

**To get the best possible results from your Zenith,** study this book *thoroughly* to make sure that you are familiar with the essential features of the camera before you start taking pictures. Refer back to the book any time there is something you are not sure of. Many operational features of this camera are unique and probably somewhat different from other cameras you may have owned. It is therefore strongly recommended that after carefully reading the instructions you shoot a 'test' roll of film, have this film processed, and examine the pictures before exposing additional rolls. This test roll will verify that you are using your new camera correctly and allow you to make any necessary changes in camera operation. Additionally, it will confirm that all the camera controls are functioning perfectly.

**N.B.** A policy of continual product development means that there may be minor differences in design or specification between your camera and these instructions.

## Specification

<b>Format</b>	24 × 36mm; using standard 35mm cassettes of 12, 20 or 36 exposure, colour or black and white film.
<b>Shutter</b>	Horizontal travelling Focal Plane type, speeded 1/30, 1/60, 1/125, 1/250 and 1/500th second plus B (brief time). Linked to self-timer giving approximately 7 seconds delay.
<b>Flash synchronisation</b>	Switch control for bulb & electronic synchronisation at 1/30th sec. through a standard 3mm co-axial socket.
<b>Viewing/Focusing system</b>	Eye-level pentaprism/instant return mirror shows upright laterally correct image. Bright Fresnel focusing screen with central ground glass/micropism spot on Zenith EM. Plain fine ground screen on E & B models.
<b>Exposure meter</b>	Built-in selenium cell with match-needle shutter/aperture read-out. Calibrated for: Film speeds 25–500 ASA/13–28 DIN, apertures f/2–f/32, shutter speeds 1/500th sec. to 30 seconds.
<b>Frame counter</b>	Additive 0–36 manual resetting type.

*continued...*

Standard Lens	<i>Helios 44m ("EM")</i>	<i>Helios 44 (E &amp; B)</i>	<i>Industar 50 (E &amp; B)</i>
Construction	6 elements in 4 groups	6 elements in 4 groups	4 elements in 3 groups
Focal length	58mm	58mm	50mm
Diaphragm type	Fully automatic instant re-open-optional manual over-ride	Manual Pre-set	Manual
Aperture range	f/2–f/16 with click stops at full and half apertures	f/2–f/16 with click stops at full apertures	f/3.5–f/16 (no click stops)
Distance scale	0.55m–Infinity	0.5m–Infinity	0.65m–Infinity
Angle of view	40°	40°	45°
Filter size	52mm screw 54mm push-on	49mm screw 51mm push on	33/35 mm screw 36/37 mm push on
Lens mount	'Universal' (42mm) thread accepts standard single pin automatic lenses and accessories	'Universal' (42mm) thread accepts standard non-automatic lenses and accessories (Some early E & B models fitted with 39mm mount)	

## Loading your camera

### Precautions

(a) Your Zenith camera accepts any standard 35mm cassette, of colour or black and white film, except Fuji type which *may* cause the film to tear due to jamming.

(b) Always load the film in subdued lighting conditions. If outdoors look for a shady area or shield the camera from direct sunlight with your body or coat.

(c) Whenever possible avoid loading in a dusty place or at the seaside where strong salty wind is blowing.

(d) When loading take care not to touch the shutter blinds.

(e) Make sure Shutter Release has *not* been set in the 'T (or Time) Lock' position. (See p. 13).

### Procedure

1. Raise the Back Lock-catch [20] and swing the Camera Back [38] open.
2. Before loading ensure rewind release mechanism has been cleared. With the EM camera

the Rewind Release Ring [3] **must be turned clockwise so that the three dots are fully lined up.**

Turn Film Transport Lever [1] through a couple of short strokes till no further movement is possible while holding back Sprocket wheel [32] lightly with finger. The Sprocket should rotate in time with the lever action and not 'free-wheel'.

3. Push up the Cassette Retaining Spindle [28] from inside the camera. Place the cassette into its chamber [27] ensuring that the cassette's projecting end faces down. Push Rewind Knob

[22] back to its original position to hold the cassette in place – you may need to turn it clockwise a little until it seats properly in the cassette spool.

4. Draw out from the cassette enough film (about 3") to insert the leader into the Take-up Spool [34].

(inset: Zenith E & B)

With the EM camera the leader can be inserted into any one of the spool's slots – with E & B cameras fix the film's leading edge under the Take-up Spool spring (turn the bottom knurled flange with finger to get this uppermost). With all models ensure that one perforation hole is caught by the Take-up Spool

tooth, also see that the Sprocket wheel [32] engages in a perforation.

5. Make sure film cassette lies flat, then alternately depress Shutter Release Button [2] and turn Film Transport Lever [1] until perforations on both sides of film are engaged by the Sprocket Wheel [32]. The film should also be taut around the Take-up Spool – turn bottom spool-flange with finger towards cassette position to take up any slackness.

**Note** – Film is advanced by sprocket drive, so it is most important for sprockets to engage film perforations properly.

6. Complete film wind, if necessary, to its limit. Press Shutter Release Button [2] then close the Camera Back [38]. Firm pressure only required on the Zenith EM as the back has a self-locking catch. With E & B models this catch [20] must be returned manually to the locking (downward) position.

7. Take up any slackness of film within the cassette (especially important with shorter than 36 exposure lengths) by slowly turning Rewind Knob [22] clockwise till slight resistance is felt. On the Zenith B the Rewind Knob is ready to hand. On the Zenith E & EM cameras, the Rewind Knob is spring-loaded and recessed within the exposure meter controls.

Zenith E & EM

Zenith B

To bring the knob into rewind position press it down firmly, twisting it slightly anti-clockwise at the same time – to re-lock the knob press down fully whilst twisting it clockwise.

8. Move Film Transport Lever [1] through two or more short strokes (letting it return to the starting position after each stroke) until no further movement is possible. Press Shutter Release Button [2].

9. Move Film Transport Lever [1] through a second series of short strokes until no further movement is possible, watching to see if the Film Rewind Knob

[22] turns while doing so. If the Rewind Knob turns it shows that the film is correctly loaded and moving properly through the camera. If it doesn't turn, and you have taken up the slack as described in step 7, then the film may not be securely attached to the Take-up spool or properly engaged by the Sprocket Wheels.

10. Now turn Frame Counter Dial [4] until the number '0' shows against the Frame Counter Index [33] and press the Shutter Release [2] once more.

● If you are not going to take photographs immediately do not wind on the film at this stage

since it is always best to leave the shutter in the fired position, just in case the camera is put away without being used for some time.

11. If you *are* ready to take photographs, wind Film Transport Lever [1] fully ... and your first film frame is in position, as shown by the Frame Counter Index [33].

#### Notes

(a) Always make sure the Transport Lever [1] has been *fully* wound. This is easiest when you move this lever in *two* short strokes. When the lever stops

during the second stroke, you are assured that the camera's film, shutter and frame-counter are all ready for exposure. Failure to wind the Transport Lever fully may result in a 'blank' exposure.

(b) To maintain accuracy in use, the Frame Counter Dial [4] *must* be zeroed only *after* winding the film/shutter. After this, every time you wind on the dial will come to rest with the next division opposite the Counter Index [33]. The counter tells you how many frames (pictures) you have taken and when it reaches 12, 20 or 36 (depending on film in use), you will need to rewind the film into its cassette and put in a new film. Colour film especially should not be left in the camera for long periods and for the best results should be processed as soon as possible after exposure. Incidentally *do* carry a spare film – nothing is more annoying than to run out of film just before the best shot turns up!

(c) The disc on the rewind knob of Zenith B models is there simply to remind you of the speed or type of film you are using – it has no effect on the camera mechanism whatsoever. To set the reminder disc hold the rewind knob, then apply finger or thumb pressure to the disc and turn it until the film speed or type lines up with the red mark.

## Picture-taking technique

Once the camera is loaded you have to consider three aspects of taking a picture – exposure, focus and composition. The first two of these are purely technical; the following sections, together with a little experience, will soon enable you to handle your Zenith with sufficient enough ease to leave you free to concentrate on the third aspect, composition, which is the artistic one.

### Exposure

Though sometimes thought to be photography's biggest problem, obtaining correct exposure is not really so difficult thanks to the latitude of modern-day films. There are three governing factors: sensitivity to light of the film (usually expressed as an ASA speed rating); shutter speed, which controls the amount of time the image is allowed to affect the film; and the lens aperture, which controls the brightness of the image falling on the film. There are two methods of obtaining the total amount of exposure required for a film of certain sensitivity under certain conditions of lighting. First is by using the exposure tables supplied with the pack of film you buy – these of course only hold

good under average subject and lighting conditions, but are usually a quite accurate guide and certainly more than adequate to begin with. A better and far more accurate method (especially important with colour slide films, as the slide is your final result) is to *measure* the brightness of a scene by means of an exposure meter. The Zenith B owner can probably work quite happily with the first method but if preferred can always purchase a separate hand-held exposure meter (our own excellent Leningrad 4, for example). For convenience and speed of use, Zenith EM and E models incorporate a sensitive built-in photoelectric meter [23] to help obtain correct exposure under widely varying conditions. No batteries are required since at its heart is a selenium cell that converts light reflected by your subject into electrical energy which directly activates the meter needle [15].

Whichever method is chosen it is recommended to use a minimum shutter speed of 1/125th second where possible. (certainly for the majority of outdoor subjects). This speed is fast enough to prevent most 'blur' due to camera or subject

movement, yet is slow enough to permit picture-taking in a wide variety of lighting conditions with today's sensitive films. If it's necessary to shoot at 1/60th or 1/30th second, hold the camera as steady as possible – ideally by using a tripod, or by bracing your arms on a nearby table or other support.

## How to use your camera's built-in exposure meter

**1. Set Film Speed** – Beneath the Aperture Indicator Dial [18] are two scales of figures. One scale marked for films rated at 25, 50, 100, 200, 400 and 500 ASA registers in the ASA speed Indicator Window [17], and the other marked in DIN ratings – of 13, 16, 19, 22, 25 and 28 registers in the DIN speed Indicator Window [16]. Turn the Aperture Indicator Dial until the speed number for your film shows against the index mark in the appropriate window. Should your film be rated at an intermediate speed, simply position the ASA or DIN index mark between the next smaller and larger number (for example for a 64 or 80 ASA film set the ASA index mark between 50 and 100, for a 23 DIN film set the DIN index mark between 22 and 25). On some E and EM cameras there are dots between the marked numbers indicating these

intermediate film speeds, but in any event if you do as described your meter will operate well within the exposure tolerances (latitude) of most film types.

**2. Aim Exposure Meter [23] at your subject** – see last paragraph on page 10.

(For a practise reading aim the meter at a brightly lit scene, or, if indoors, at a nearby lamp – making sure your fingers do not obstruct the meter window). As you do so you will note the Exposure Meter Needle [15] moves to a certain position and then stops. Holding your camera in this position you now ...

**3. Match the Needle [15]** so that it is centred beneath the Meter Cursor [14] by turning the Shutter Speed Indicator Dial [19].

**4. Your Light Measurement or Reading has now been taken.** Each combination of lens opening (f/number) and shutter speed shown on the Aperture Indicator Dial [18] and Shutter Speed Indicator Dial [19] will give the right amount of exposure. For example in the illustration shown, these scales show that correct exposure will be obtained with a shutter speed of 1/125th of a second and at a lens opening of f/8 or a speed of 1/250th of a second and a lens opening of f/5.6 etc. The combination chosen will of course depend on the subject to be photographed (see p. 16) and the appropriate shutter speed and aperture should be set on the camera and the lens.

**Note:** Only the numbers appearing in *black* on the Shutter Speed Indicator Dial [19] can actually be set on the camera. The Red numbers 15, 8, 4 and 2, appearing next to the Black numbers 30–500, represent fractions of a second. '15' is 1/15th second, etc. These appear for information purposes only, say for when using your camera's meter to determine exposure with cameras lacking a built-in meter. The set of Red numbers 1, 2, 4, 8, 15 and 30 which are furthest from the Black numbers 30–500 on this Dial [19] show exposure time in whole seconds and can be used in certain circumstances

(see 'Time Exposure', p. 12) when so indicated by the exposure meter reading (See 'In extremely dim light' following).

### Helpful hints for better exposure

Remember that your exposure meter measures all the light that reaches its cell and *'averages out'* the brightness or contrast range before giving a reading. With subjects of average contrast (e.g. scenes lit from the front, or at an angle from the side, where there are no heavy shadows and dark and bright areas are fairly balanced) the right amount of exposure is indicated automatically. However, to obtain the best results with subjects of widely varying brightness range it is wise to take a few precautions.

● If your main subject is much lighter than the background (e.g. a portrait of an illuminated face against a darkened doorway, arch or foliage) or... if it is much darker than the background (e.g. a person, boat or chalet set against a seascape or mountain scene directly lit by the sun) move right up to your main subject until it fills the viewfinder, and take a close-up reading with the exposure meter. Set the appropriate exposure combination

found from this reading on your camera and lens controls before returning to the original viewpoint to take the picture.

● Take a substitute reading. Sometimes a close-up reading is not possible: if this is the case aim the exposure meter at an alternative subject of average contrast under the same lighting (the back of one's hand is a good example or ideally a sheet of neutral grey card). Again, use an appropriate combination from this reading on the camera and lens controls. Alternatively, close the lens aperture by 1 to 2 stops (f/no's) as compared with a straightforward meter reading of the former subject and open up the aperture by 1 to 2 stops to that indicated for the latter subject – this too will prove more correct in most circumstances of this nature.

● Always be careful to aim the exposure meter exactly in the direction of the subject. Inadvertent tilting of the camera, into the sky for example when taking landscape views, can falsify the reading and in this case lead to under-exposure. It is best to aim the meter *downwards* slightly when taking landscapes and similar outdoor pictures to avoid adverse influence on the reading from the bright light of the sky.

● Against the light, unless you're purposely striving after a silhouette effect, with your main subject very deep in shade against full highlight detail, then you must open the lens aperture by at least one stop to that indicated by an exposure meter reading.

● If using colour slide film, avoid subjects with great brightness differences. Even a close-up reading of the shadow areas often results in excessive exposure for the sunlit areas, which then appear too light and burnt out when the slide is projected. A straightforward average brightness reading under conditions of uniform frontal or side angled lighting yields slides of good colour saturation which correspond most closely to the natural colour impression.

● In extremely dim lighting, the Exposure Meter Needle [15] may rest near the right-hand edge of the transparent window. Should this occur, place your hand close in front of the Exposure Meter Window [23] and watch the needle carefully. If the needle moves when you block the meter cell the exposure meter is able to function in the existing light – remove your hand and determine exposure in the normal way. However, if no needle movement occurs when you place your hand in front of the meter cell the existing light is insufficient and the exposure meter cannot be used. In this event, either a time exposure or use of a flash gun is recommended.

# Setting the camera and lens controls

## Shutter Speeds

Lift the Shutter Speed Dial [5] and turn it until the required speed aligns with the index dot in the centre of the dial (see p.9). Release the dial, making sure it drops fully home and is correctly lined up, and the speed will be set. Shutter speeds may be selected before or after the Film Transport Lever [1] has been wound. However, the following points *must be observed* to avoid mechanical damage: (a) Always *lift* the Shutter Speed Dial before turning it to another speed and *lower* it *fully* before shooting; (b) Always turn the Shutter Speed Dial to one of the *marked* speeds (30, 60, etc., that indicate fractions of a second, or B, that indicates a hand-controlled time exposure) – NEVER to a position between marked speeds, and finally (c) DO NOT turn the Shutter Speed Dial the short distance between B and 500.

## Long Exposure Times (Time Exposures)

Time exposures of one second duration or longer, enable you to take photographs in lighting conditions that would be too poor for normal picture-taking, e.g. city streets at night or dimly lit

interiors. To take a time exposure with your Zenith set the Shutter Speed Dial [5] to 'B'. At this setting the Shutter will remain open for as long as the Shutter Release Button [2] is pressed down. A sturdy tripod is really essential for this type of work, though sometimes it is possible to find an alternative firm support (a street bollard or church pew, for example). A cable release, preferably the locking type, is also recommended for extra steadiness. If such a release is not available the shutter can be kept open for extended periods, via the 'T' lock, simply by pressing the Release Button [2] down firmly and turning at the same time in an anti-clockwise direction, (as seen from top of

camera) until it stops. The shutter will remain open for as long as desired and is closed on completion of exposure by pressing down the Release Button once more and returning same, clockwise, to its normal position. To reduce the risk of vibration it is recommended that a piece of black card (or even one's hat) be held in front of the lens as the Release Button is pressed and turned – the lens is then uncovered for the required time (using a stopwatch or slow count) and then recovered to end the exposure while the Release Button is returned to its normal position. Obviously this procedure only applies to long exposures of several seconds.

**Note** After using the 'T' or Time lock on the Release Button always make certain that the Release Button [2] is turned fully clockwise and,

with the Zenith EM, that the Rewind Release Ring [3] is still turned fully clockwise and the three dots are properly aligned. This will ensure correct operation of shutter and exposure counter in subsequent pictures.

Your camera's Tripod Bush accepts a standard  $\frac{1}{4}$ " Whitworth screw. When fitting a tripod or other bush mounted accessory (e.g. flashbar) care should be taken to see that this is screwed in just finger-tight only (this applies to the carrying-case retaining-screw also). If there is a safety locking-nut on the accessory, turn the main screw up to three revolutions only, then hold it in position and lock into place with the safety nut.

## Apertures

First the Helios 44M, the standard lens supplied with the Zenith EM camera; this is designed to be used in Automatic or Manual mode. When the Auto/Manual Switch [36] is set to 'A', the aperture remains fully open for viewing and focusing and closes down automatically to a pre-selected f/number value when the Shutter

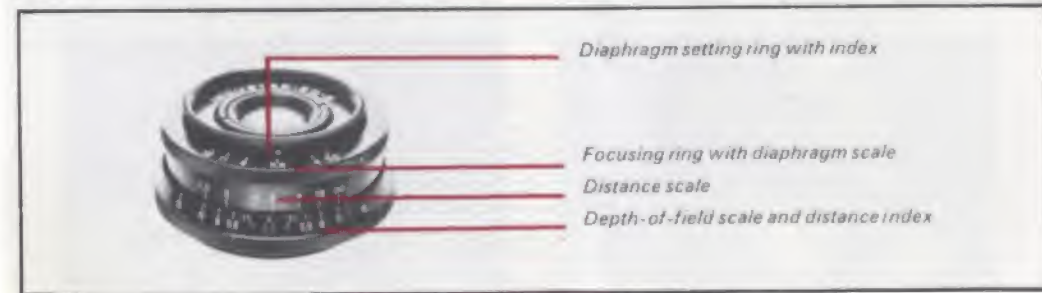

Release Button [2] is pressed down. When the Auto/Manual Switch [36] is set to 'M', the aperture closes down immediately to whatever f/number has been selected on the Aperture Ring [24]. Thereafter apertures are changed manually by moving the Aperture Ring into any of its 'click-stop' positions. Normally the lens would be used in Automatic mode, in which case the lens opening required (f/2, f/2.8, f/4, etc.) is selected by turning Aperture Ring [24] until that f/number (or a position mid-way between marked lens openings, if so indicated by the Exposure Meter Aperture Indicator Dial [18]) aligns with the red Distance/Aperture Index Mark [11] (see p.9). As soon as pressure is taken off the Shutter Release Button, the aperture automatically returns to its wide-open position.

For Zenith E & B cameras the standard lenses are the Helios 44 with pre-set aperture mechanism or the Industar 50 with a purely manual, non-click-stopped mechanism. Operation is as follows:-

**Helios 44** – Turn the Diaphragm setting ring (which has click-stops at full apertures) until the f/number required is set against the red index dot on the front ring of the lens. Now turn the Pre-set Diaphragm Ring until its red index dot is also aligned with the dot on the front ring and the lens is at full aperture for viewing and focusing. After

focusing turn the Pre-set Ring as far as it will go in a clockwise direction (as seen from top or back of camera) – this closes the lens down to the pre-selected aperture in readiness for picture taking. With practise you do not even have to look at the lens after initially setting the aperture required – with the camera held to the eye, simply turn the Pre-set Ring fully *anti-clockwise* for wide aperture viewing and focusing, then turn it fully *clockwise* after focusing to take your picture, assured that the aperture will be closed down to its predetermined setting. You can even change apertures without taking the camera from your eye; first set the lens to full aperture, then turn Diaphragm Setting Ring – each click to the left selects one larger aperture, each click to the right selects one smaller aperture. Remember of course to close down to the newly selected aperture with the Pre-set Ring as previously described.

**Industar 50** – Turn the Diaphragm Setting Ring at the front of the lens until its index dot aligns with the figure 3.5 on the Diaphragm Scale, viewing and focusing at eye level. You must now take the camera away from your eye, since the aperture required for picture taking can only be set after focusing (it is usually too difficult to see or focus clearly when the lens is closed down, since less light enters the viewfinder).

## Choosing shutter speeds and lens openings

As seen from an earlier illustration, your exposure meter indicates various combinations of shutter speed and aperture that will each produce good results under given conditions of lighting and film sensitivity. However, you will often need to select a particular shutter speed or aperture to suit your subject so how do you choose? For example, the suggested shutter speed of 1/125th second, while fast enough to stop most normal subject movement (people walking etc.), would not be

*At 1/30th second*

enough to freeze the really fast action of subjects such as children at play, sports events or racing cars – here a speed of 1/250th or 1/500th second would be best. Again, if taking a landscape type picture, a small aperture of say f/11 or f/16 would be needed to obtain maximum sharpness (see Depth of Field). Summarising then; with moving subjects, choice of shutter speeds is of most importance, to stop the motion use the fastest speed possible that lighting conditions will allow;

*At 1/500th second*

where you need your subject to be sharp over a long range from foreground to background, then choosing a small lens aperture is more important. It's worth knowing too the relationship between shutter speed and aperture settings (especially important if using exposure tables, as these generally detail changes of aperture according to lighting conditions at a fixed shutter speed – most commonly our suggested 1/125th second). These settings are so designed that altering from one figure to another on either scale, will double or halve the amount of light reaching the film. An aperture of f/5.6 is wider than, and will transmit twice as much light as, an aperture of f/8, and at the same time is smaller than, and will transmit half as much light as, an aperture of f/4. Likewise a shutter speed of 1/125th second is slower than, and will transmit twice as much light as, a speed of

1/250th and is at the same time faster than, and will transmit half the amount of light as, a speed of 1/60th second. Thus if you start from a given combination, say 1/125th at f/8, and you decide that a shutter speed of 1/250th would be better for the subject and you want to finish up with the same amount of exposure, you will need to compensate for the fact that only half the necessary light is reaching the film by opening the aperture one division to f/5.6. If you had decided that 1/500th were the best speed you would need to open the aperture by two divisions (from f/8 to f/4) since 1/500th is two divisions up from, or a quarter the speed of, 1/125th second.

Remember though that all combinations of shutter speed and aperture are a compromise. There is really no 'correct' exposure for any subject, it all depends on the effect you want.

Aperture	2	2.8	4	5.6	8	11	16
							
Light Ratio	1	1/2	1/4	1/8	1/16	1/32	1/64

## Viewing and focusing

First make sure your lens is securely attached to the camera by turning it clockwise until no further movement is possible.

Look through the viewfinder eyepiece [30] and you can feel safe in the knowledge that there'll be no parallax problems (no more cut-off heads in close-up portraits and the like) as you are viewing and focusing, by means of a ground-glass screen,

*Out of focus*

*In focus*

through the actual lens that takes the finished picture. There's a built-in safety margin of course, in common with many other modern single lens reflex cameras, the viewfinder showing an overall area somewhat smaller than the total film area. This ensures that *everything you see in the viewfinder appears* in the finished picture despite the fact that slidemounts and masks in printing equipment actually cover part of the film's image.

Focusing should always be carried out with the aperture wide open, unless of course you want to preview 'depth-of-field', so follow the previous instructions concerning aperture operation for the three standard lenses. With the camera held to your eye turn the Focusing Ring [12] towards the right for close distances or towards the left for far distances, until the subject is sharp and clear on the large ground-glass screen. The Zenith EM camera has in addition in the centre of its screen, two aids for speedier critical focusing, a **microprism spot** which is composed of literally hundreds of tiny

prisms that distort and accentuate an out-of-focus image. Simply focus the lens until you obtain a single undistorted image at the centre and you are at the point of sharpest focus. This microprism works well for the majority of subjects and conditions but for subjects lacking in contrast or colour the **fine ground-glass collar** around the central spot is probably more helpful – it's quite handy when using long telephoto and wide angle lenses too. (Aim your camera at this instruction book from about 2 feet away and you'll see how these focusing aids work). You can of course also use the Distance Scale [26] of your lens, which is calibrated in metres, to set the focus. Generally there's no need to check distance, it's almost always easier to use the viewfinder; the only time it becomes necessary is when taking flash pictures (see p. 26) or when 'depth-of-field' is important.

● The Red 'R' just to the right of the Distance Indicator [11] on the Helios 44M shows the correction required for infra-red films. When using infra-red films, first focus in the normal manner, and note the indicated distance. Then move the Focusing Ring [12] so that that distance is now aligned with the Red 'R'. Remember – this is needed only when using infra-red films which are sensitive

to light rays which focus at a slightly different plane than ordinary light rays.

● A 16mm diameter prescription lens can be inserted into the Viewfinder Eyepiece [30] and held in place by Retaining Ring [31]. Spectacle wearers may find this helpful for critical work. (Contact T.O.E. Service Dept., if difficult to obtain this item).

## Depth-of-field

All photographic lenses, when focused on a given subject, will show some objects in front of and behind that subject more or less sharply. This 'range' of extra sharpness is called 'depth-of-field' and varies with different lenses; it's greatest with wide angle lenses, and least with telephoto lenses. With any lens, you'll find your depth-of-field is always **greater** (more things in focus) **at small lens apertures** such as f/11 or f/16 and **lesser** (fewer things in focus) **at larger lens apertures** such as f/3.5, f/2.8 or f/2. Depth-of-field is also greater in cases of more distant subjects than it is with close-up subjects and increases nearly twice as much beyond the subject, your main point of focus, than it does in front of the subject (towards the camera).

If your picture is such that you want both nearby and distant objects to be in sharp focus then generally the smallest possible aperture should be used. However, the aesthetic quality of a picture can often be improved by having the principal subject in sharp focus while other objects in the

scene are soft and out-of-focus. Here a larger aperture is necessary to produce the 'differential focus' that de-emphasises distracting background and/or foreground detail and thus isolates, and concentrates your viewer's attention on, the principal subject.

You may want to 'preview' depth-of-field prior to exposure. This can be done in two ways, first by pressing the Shutter Release Button [2] smoothly until it reaches the definite stopping point, just before firing the shutter. This closes the aperture down to its pre-set value and enables you to get an idea (despite the dimness) of what will or will not be sharp – the final photograph will be at least as sharp if not sharper than the viewfinder image. The second method is to turn the Auto/Manual Switch [36] to the 'M' position which has the effect of manually closing the aperture down to the pre-selected lens opening – this is probably easier to master than the first method but you must remember to return the Switch after use to the 'A' position ready for normal operation. With the Helios 44 and Industar 50 lenses, follow the previous instructions regarding aperture operation and you'll see that even though they lack the automatic aperture closing feature, depth-of-field can still be previewed prior to taking the picture.

### Using the depth-of-field scale [25]

The scale consists of the aperture numbers repeated each side of the Distance Index [11] and shows, at any given focus distance, the nearest limits and furthest limits of acceptable sharpness. Taking the Helios 44M lens as an example, if this is focused at 4 metres, the depth-of-field stretches from 3 metres to 6 metres at an aperture of f/5.6 while at an aperture of f/16 objects from 2 metres to infinity ( $\infty$ ) will be acceptably sharp in the final picture. **Note:** For the sake of reading clarity some

At f/2

At f/16

figures are omitted from the scale; however, it's a simple matter to 'fill in' those missing if you remember they follow the aperture sequence exactly, with those proceeding left from the index [11] showing the near limits of sharpness, and those proceeding right showing the far limits.

### Now for some practical examples

(a) You're taking a landscape view where you want everything needlesharp from the foreground all the way to the background. Easy you say, close the aperture right down to f/16 – the snag is that the sky has clouded over and the light is too poor to use

this aperture at a reasonable shutter speed. The remedy – obtain the maximum depth-of-field required with the minimum of 'stopping-down' (decreasing aperture size). Focus through the viewfinder on the closest object and note the distance (say 3m) registered against the Index [11], then focus on the most distant part of your subject and note this distance (say 10m) also. Now look at your lens and move the Focusing Ring [12] until both distances appear just between an identical pair of aperture numbers (f/8, in above example), on the Depth-of-Field scale [25]. Set the lens to the aperture thus found, use your exposure meter to determine the correct shutter speed for an exposure at this aperture, then set this speed on the Shutter Speed Dial [5]. Everything between the two distances (3 to 10 metres) shown by the matching aperture numbers (f/8) on the Depth-of-Field scale [25] will appear sharp in the final photograph.

(b) If you need absolute maximum depth-of-field at any given aperture focus on the 'hyperfocal distance'. This is found by aligning the infinity mark ( $\infty$ ) against the Distance Index [11]. The distance then found to be aligning with the near limit of depth-of-field for the aperture required will be the 'hyperfocal distance'. If the lens is now refocused so that this distance aligns with the

22

Index [11] everything will be sharp from half the distance to infinity.

(c) To obtain a 'differential focus' effect, determine the closest and most distant parts of your subject as described in example (a) above, then refocus the lens so that the distance of the important part of your subject aligns with, or is near to, either the near or far limits (according to whether you want foreground or background out-of-focus) on the Depth-of-Field scale [25] when using a largish aperture, say f/4. Set lens and camera controls as necessary and you'll be assured of obtaining a picture of high subject impact.

Here we can see that the 10 metre focus setting is in fact the hyperfocal distance for an aperture of f/8 which gives us the maximum depth-of-field possible from that lens, extending from half that distance (5 metres) to infinity

## Taking the picture

Poor first-time results are largely attributable to camera shake, so it's *very important to hold* the camera steady *using both hands*. You will probably find it most convenient to grip the camera firmly with your right hand and fire the Shutter Release Button with your right fore-finger. This way your left hand can easily turn the Focusing Ring and give extra support at the same time. *Always* press the Shutter Release Button downwards smoothly and firmly – **NEVER** jab at it. (On the Zenith EM make sure you do not accidentally restrict movement of the Shutter Speed Dial while depressing the Release Button).

**For each Successive Exposure** . . . just move the Transport Lever until fully wound and you're

Note the extra support the left hand gives without obstructing Meter Window [23]. Note also 'correct' finger position for smooth release of shutter.

ready for your next shot. If lighting conditions have not changed it is only necessary to frame the subject, focus and fire the shutter. If taking a photograph in a slightly different direction or if the sun clouds over, take a further meter reading or consult film exposure tables and make any adjustments to camera and lens controls that might become necessary before firing the shutter.

**NOTE.** Keep an eye on the Frame Counter [4]. When this registers a figure indicating that the entire length of film has been exposed, or if the Film Transport Lever cannot be turned, it is time to rewind the film into its cassette ready for processing. DO NOT try to get an extra exposure – if the Transport Lever is wound forcibly the film may be damaged and disengage from the cassette making it impossible to rewind.

## Removing exposed film

**(1) Before attempting to rewind a film put the cap, supplied with your camera, back on the lens.** This is simply a precautionary measure to prevent any portion of the last frame being exposed to light, since the Rewind Release has the effect of firing the shutter even if, as sometimes happens, the Transport Lever is only partly wound when the end of the film has been reached.

*Zenith EM rewind release*

**(2) Releasing the film for rewinding.** Zenith E and B models have a Rewind Button (see below) which must be pressed and held down firmly during the entire rewinding operation. The Zenith EM has a locking device which permits rewinding without constant application of pressure. To engage it first press the Shutter Release Button [2] then turn the Rewind Release Ring [3] fully anti-clockwise. Make sure the Ring is turned until no further movement is possible and you'll then be able to rewind the whole film quite freely.

**(3) Rewinding.** The Rewind Knob [22] should be

*Zenith E & B rewind release*

gripped firmly and rotated in a clock wise direction (as indicated by the engraved arrow). While resistance is felt you are rewinding the film back into the cassette (the knob will turn freely without resistance when the film has been fully rewound).

● On Zenith B models the Rewind Knob is ready to hand. On Zenith EM and E models it is spring-loaded and recessed within the exposure meter controls and must therefore be raised first into rewind position by gently pressing against the top of the knob and turning it anti-clockwise at the same time.

● Remember the Rewind Release Button on Zenith E and B models must be held down firmly until the film has been fully rewound.

(4) Having rewound the film, remove the camera from its case, raise the Back Catch [20] and swing the Camera Back [38] open. Pull the Rewind Knob [22] upwards fully and take the cassette of exposed film out of its Chamber [27]. Your film is now ready for processing.

(5) The camera can now be reloaded (after observing precautions on p. 6). If you don't want to reload till a later date return the Rewind Knob to its 'closed' position.

*Rewind release set for film advance*

## Taking flash pictures

When the light is poor some form of auxiliary lighting will be required. This is why your Zenith has a built-in synchroniser which enables you to use either electronic or bulb/cube flashguns. There are pros and cons for each type – if you think you will only be taking occasional flash pictures (at party times etc) then a bulb or cube gun is best, since its advantages of low initial cost, compactness and lightness in weight may well outweigh the nuisance factor and high running costs of having to use a new bulb for each picture (or a new cube for each four pictures). For the more serious photographer an electronic gun is the best bet, since in many cases nowadays it too offers compactness plus almost unlimited life (the tube lasts for *several thousand* flashes and gives dozens or even hundreds of flashes on a set of batteries – some can even be powered by mains supply or mains rechargeable nickel-cadmium batteries that further cut down on running costs). More advanced models even boast a built-in mini-computer which automatically regulates the

duration of the flash according to subject distance for perfect exposure. We recommend you to consult your Zenith camera dealer for advice on the best type of gun to suit your needs – here we can only give guidance on the procedure and technique of flash photography

1. Make sure the Flash Synchronisation Selector [6] is fully aligned with the appropriate setting 'X' for electronic flash, 'M' for bulb and cube flash

2. The Shutter Speed Dial [5] *must* be set at  $1/30$ th second whether using bulb/cube or electronic flash.

● The shutter will not synchronise correctly (i.e. will not open at the time the flash is at its brightest) if the wrong setting or any other shutter speed is used

3. Small lightweight flashguns may be safely clipped into the Accessory Shoe [13] on top of the camera. Some electronic guns being heavier may need a separate mounting bracket or 'flash bar' which screws into the Tripod Bush [35] at the bottom of the camera.

4. Plug your flash gun into the Flash Synchronisation Socket [7] making sure its tip is pushed in firmly.

● The short burst of light from a flash is too brief to be measured under normal circumstances, so exposure for flash photography is governed by the sensitivity or speed rating of the film in use, light output or power of the gun and its distance from the subject. This is why most modern flashguns, of whatever type, have calculator dials or scales on them which indicate the correct aperture according to film speed and distance.

Obviously the type of calculator dial or scale will vary with each make of gun, so consult the instruction book supplied with your unit, or your dealer for exact information – the general operating rule however is ...

5. Look through the viewfinder and focus on your subject. You can then find from the calculator dial/scale the correct lens opening for the actual camera-to-subject distance that is shown by your lens' Distance Scale [26]. The Aperture Ring [24] must then be set accordingly. Remember that with the Helios 44 and Industar 50 lenses the aperture must be closed down manually after focusing.

● Do not press down on Shutter Release Button [2] unless actually taking a flash picture since this will fire the flash even if the Transport Lever [1] has not been wound. However, there will be no loss of film should this happen.

● If the flash unit does not fire when you press the Shutter Release Button [2] make sure that the lead is securely plugged into the Flash Synch. Socket [7] and that the Selector [6] is properly set in the appropriate position. With electronic guns also check that unit is switched on and with bulb or cube guns that, (a) the bulb/cube is pushed fully home and (b) the battery is still fresh (most such guns have a battery check device).

● Always make sure Transport Lever [1] is fully wound before a new bulb is inserted into a bulb flash gun that is connected to the camera.

● When not using flash, the Synchronisation Selector [6] may be set in either the 'X' or 'M' position.

## Using the self timer

Your Zenith camera has a built-in self timer that trips the shutter after at least a 7 second delay thus enabling you to get into the picture yourself. Here is how to use it ...

1. Support the camera on something firm, a tripod is best, but any stable surface such as a nearby table or shelf will do.

2. All main controls are set as normal, i.e. Wind Film Transport Lever [1] then frame and focus on the general subject area. Select the required shutter speed and close the lens opening down to the required aperture (with the Zenith EM you must first set the Lens Auto/Manual switch [36] to the 'M' position).

3. Turn the Self-Timer Lever [10] downwards in an anticlockwise motion until no further movement is possible. (As you move this Lever on the Zenith EM camera you'll see an 'M' sticker beneath it which is there simply to remind you to set this camera's lens to the Manual position as previously mentioned.

4. Now press the Self-Timer Release Button [9] and move into the picture area as quickly as possible. The lever [10] will slowly return to its normal

position releasing the shutter automatically during its travel.

● Make sure the Self-Timer has been *fully* wound before pressing the Release Button [9] as otherwise the shutter will not operate. (If this happens just move the Self-Timer Lever downwards again – fully this time! – and press the Timer Release Button again.

● If you decide not to use the Self-Timer after moving the lever down, simply take your next picture by pressing the Shutter Release Button [2] as normal. Then before winding Film Transport Lever [1] press the Timer Release Button [9] and the timer will return to normal position. NEVER

leave the self timer lever in the 'wound' position for extended periods.

● An extra tip: if the shutter speed is set at 'B' and the self-timer mechanism is used you will obtain a 'time exposure' of between 1 and 5 seconds. The actual time of exposure will vary from camera to camera, so we suggest you determine the time for your particular camera, as it may well come in handy to know when taking pictures in dimly lit conditions.

● If required, the Self-Timer can also be used in conjunction with a flashgun (of either type) observing of course the previous notes on flash photography.

## Changing lenses

Your Zenith camera is fitted with a Universal 42mm thread mount (except for some very early Zenith B and E models which had a 39mm thread mount). A range of 42mm mount preset diaphragm lenses, designed primarily for the Zenith E & B but usable on the Zenith EM in Manual mode, is available from your dealer. You are also able to choose from literally hundreds of lenses made both by other camera manufacturers and independent lens makers.

To remove a lens just grip the whole barrel firmly and give it about three turns to the left (anti-clockwise). To attach a lens simply screw it firmly into the camera's mount in a clockwise direction; when it stops, give it a slight extra twist to ensure that it is securely attached. **Note** – when refitting lenses with an auto-manual control, such as the standard lens fitted on the Zenith EM, make certain that the lens is set to the 'A' position before taking further photographs. This ensures that you will be able to frame and focus easily.

● Thread mount lenses, particularly those of different manufacture to the camera, may

sometimes fit with the aperture and distance scales slightly to the right or left of the centre position. This does not indicate any defect in your camera or lens and in no way affects the camera/lens operation.

● Take care not to expose your camera's interior to dust, dirt or moisture when the lens has been removed. Always replace the lens in the body as soon as possible (or use a body cap obtainable from

your dealer). When removing or storing lenses, protect them from accidental damage by placing them face down and if possible, attaching a rear lens cap (again obtainable from your dealer but usually included with accessory lenses). This latter point is particularly important with lenses having an automatic aperture mechanism since you should always avoid putting undue pressure on the metal control pin at the rear.

● Only standard Automatic Lenses with a single pin operating the aperture mechanism can be used with the Zenith EM. Lenses designed specifically for use with more advanced methods of electrically or mechanically coupled automatic systems, which have extra keying levers on the mounting flange, should not be used (see illustration).

● All modern high-quality lenses such as that fitted to your Zenith camera are made from special grades of optical glass. During the manufacturing process small bubbles almost inevitably occur within the glass, but these have no adverse affect whatsoever on the functioning of the composite photographic lens.

*Not for use with Zenith EM*

*For Zenith EM*

## Caring for your camera and accessories

Your Zenith is a ruggedly-built camera designed to provide many years of dependable performance. If you want the longest service and best performance, always treat your camera and accessories as you would any precision instrument – with care and respect!

● **First and foremost keep them clean!** Your camera should be kept in its carrying case whenever possible. The case is designed to permit all operating functions, except loading/unloading, to be performed while the camera is inside. It will help protect your camera and lens from dust, dirt, moisture and light knocks against hard surfaces – the natural enemies of all cameras.

The Zenith EM camera can be carried outside its case if preferred [your dealer can supply an accessory neck strap which attaches to the body eyelets [8] & [21], but if it is, take extra care to guard it against bumps and jolts. Remember too that on the beach sand and sea-spray somehow seem to get everywhere; even a closed carrying

case needs extra protection (a large polythene bag is quite good).

The lens in particular, which can be quite easily scratched, should be protected at all times – an Ultra-Violet filter is very good here since it needs no exposure correction and can therefore be kept on the lens almost permanently as protection against dust and the weather.

● **When cleaning becomes necessary** as it almost inevitably will with outdoor use, any accumulated dust in the camera body can be lightly brushed away with a soft brush, or preferably blower-brush. Don't forget to keep the Exposure Meter Window [23] clean by the same means, as otherwise accuracy of the meter is likely to be impaired. Exterior metal parts can be cleaned with a soft clean cloth moistened with ether or absolute alcohol. **NEVER** touch the lens or mirror surfaces with the hands—fingerprints diminish optical efficiency and due to natural skin acidity may in

time damage the delicate optical coating of the lens and surface silvering of the mirror – *only* an air blower (bulb type or similar) should be used for removal of dust. Any stubborn traces of dirt or condensation left on the *lens* after this can be removed by lightly wiping over the surface with a clean soft piece of lint-free fabric or cotton (or a pad of surgical cotton-wool on the end of a matchstick) that has been dampened with absolute alcohol, ether or ether spirit mixture; any smears can be removed with a dry soft cloth. **NO ATTEMPT** should be made to clean the mirror or viewing screen by wet means – air cleaning *only* is allowed and this is usually best left to a specialist.

● **Protect your camera from extremes of heat, or humidity.** Never leave it inside the glove compartment or boot of a car – on a hot day temperatures of 100 °C can build up – and most important **NEVER** leave your camera out in the open sun. Heat is bad for the film and camera lubricants and the lens can act as a burning-glass causing damage to the camera's interior. Also prolonged exposure to intense sunlight can adversely affect the Selenium Cell that powers the meter on Zenith EM and E Models.

● **Storage** – If your camera is likely to be left unused for some time (several days or more) always make sure the shutter and self-timer mechanisms are released first. When wound, these mechanisms are under strong spring tension; by releasing them you eliminate the tension and avoid any undue strain.

Keep the camera enclosed in its carrying case with the lens cap on too. Do not store in humid conditions unless a suitable drying agent, such as silicagel in a sealed container, is placed alongside it.

If you do not use your camera regularly, and especially before going on holiday or an important occasion such as a wedding etc., we recommend that you run off a test film making sure that all variable settings including the self-timer mechanism are used.

## Trouble shooting

Your Zenith camera is designed to give you thousands of pleasurable photographs. Like any precision instrument, your camera's controls must

be operated correctly for best results. Should you at any time experience any apparent malfunction with your camera check the following handy trouble-shooting chart. Chances are you will be able to solve your own problem on the spot.

If this happens . . .	Here is why . . .	And how to correct it . . .
Prior to loading. Film Sprockets [32] free-wheel and do not turn when Transport Lever [1] is turned	Rewind Release Ring [3] (Zenith EM Only) not turned fully to the right (clockwise).	Turn Rewind Release Ring completely to the right until no further movement is possible.
After loading, Frame Counter [4] skips two or more numbers after being set to '0' position.	Film Transport Lever [1] not fully wound before counter is set to '0' position.	Advance Transport Lever fully before setting counter to '0'
Shutter Release Button [2] does not trip shutter.	Film Transport Lever [1] not fully wound	Always operate Transport Lever in two strokes. It will stop mid-way during the second stroke assuring you that shutter is completely wound
Exposure Counter [4] 'skips', counting incorrectly.	See above – or Counter set before Transport Lever was wound	See above – always wind set Transport Lever before setting counter

### If this happens . . .

### Here is why . . .

### And how to correct it . . .

Film Transport Lever [1] does not stop after two or more strokes.

Rewind Release [3] (Zenith EM only) not turned fully clockwise so that three dots are lined up. Shutter Release Button [2] not turned fully clockwise (to the right).

Turn Rewind Release Ring and Shutter Release Button completely to the right, until no further movement is possible.

Self-Timer does not trip shutter.

Self-Timer Lever [10] not fully wound. Transport Lever [1] not wound.

Wind Self-Timer Lever fully until lever points downwards with no further movement possible. Always ensure Transport Lever is fully wound before setting Self-Timer Lever.

Lens does not close down to indicated aperture when Self-Timer is used (EM only).

Auto/Manual Switch [36] on lens not set on 'M'.

Move Auto/Manual Switch to 'M' whenever Self-Timer is used.

Flash unit fires when Shutter Release is partially pressed, or does not fire.

'X' or 'M' Indicator [6] not aligned correctly.

Move Indicator fully to 'X' position for electronic flash or 'M' position for flash cubes and bulbs.

If anything should go wrong with your Zenith and the preceding chart has not got you out of trouble, **NEVER** attempt to mend it yourself – you could turn a minor adjustment into an expensive repair.

Remember that your Zenith and its accessories are backed up by top-class service facilities where factory-trained specialists are available to put things right, quickly and inexpensively.

## Composition or . . . taking better pictures

Composition is concerned with what you put into your picture and where; its final control lies in *your* hands. A slight amount of extra thought and/or effort on your part can often turn what would have been an otherwise ordinary-looking photograph into one which is stunningly attractive. There are so many factors involved that probably thousands of books have been written on this aspect alone – however here are some basic picture-taking tips that will help you take better pictures starting right from your very first roll of film . . .

● **Isolate your subject** – Concentrate your viewer's attention on the subject of your photograph, move in as close as possible, filling the viewfinder frame and eliminating all extraneous foreground and background detail. Remember that you can safely compose direct in the viewfinder, you see what the lens sees (in fact there'll be a little more actual film image as previously mentioned due to the viewfinder's built-in safety margin). Another way to eliminate extraneous detail and gain impact for your subject is to use the 'differential focus' technique described on page

20. With some subjects (e.g. sporting events, wildlife, distant objects of all kinds) you're unable, or it's inconvenient, to get in close – here a *telephoto lens* scores as it "compresses" space making distant objects appear closer. Taking in less of the field of view it also teaches you to be selective in choice of subject and viewpoint.

● **Keep it simple** – a few bold masses nicely contrasting with each other are more pleasing to the eye than a confusion of small detail. Aim to achieve balance more than symmetry. Have objects of uneven size balancing each other rather than a geometric arrangement of equal sized objects. Choose surroundings and backgrounds carefully – those that complement your subject rather than take interest away from it. A person standing in front of a fussy background such as a building (unless it is 'thrown out of focus') is seldom as attractive as a close-up of the same person against a background of trees or clear sky.

● **With colour** – Complementary colours suggest harmony – clashing colours suggest conflict. Pastel shades with a tiny, brightly-coloured accent

can be more effective than masses of strong colour. The camera is not as selective as the eye, which is why a bed of mixed flowers is rarely a good subject for colour film.

● **Try to include something in the foreground of landscapes.** A picture of distant scenery will often be improved just by a bush, a rustic gate or trees in the foreground. People too, add life and impact to all kinds of outdoor photography – a photograph of a winding country lane is *good*, add

a person walking down that lane and the picture may very well be *great*. (If nobody's around get into the scene yourself by using the camera's self-timer).

● **Shoot from higher and lower angles –** Taking pictures of small children? Get down to their level – literally. Kneel down, so that your camera is at eye-level with the child (instead of aiming down). The result, again, will be a much more interesting, natural-looking photograph. Taking pictures of a group of people? See if there

are stairs nearby so you can shoot from a higher angle. Each person in the group will be more visible than if you shot them at eye level.

● **Avoid tilting the camera to include the top of a tall building.** In the finished picture it will look as if the building is falling over backwards. Always use a wide-angle lens for best results when you want to take in a broader field of view than is possible with your standard lens. (Sometimes of course perspective distortion like this can be used to good effect for subject impact).

● **Ask your subjects NOT to look at the camera –** Pictures of people are usually much more natural looking when the people are doing something, and looking at what they're doing. A picture of a do-it-yourself handyman absorbed in a project is going to be more interesting – and a better photo – than a picture of the same person standing up, staring at the camera. (Chances are, his expression will be a lot more relaxed and natural too). When your subject has forgotten about the camera is when you'll probably get your best pictures.

● **Don't be afraid to experiment –** For example a silhouette of a person watching a sunset can be much more attractive than an ordinary photograph of the same scene.

● **Look for unusual subjects and viewpoints.** A picture of a famous building or monument may well be attractive in its own right – so take it, but also take a picture of people looking at it or a reflection of it in a nearby window or even some close-up details of it against a clear sky etc. Bad weather can sometimes lead to very good pictures! A child gazing through a rain-splashed window, the play of bright lights in the water at the curbside, a figure walking through a snow-storm. Use your imagination, make your own 'rules' as you progress. Your pictures will be far more interesting, far more eye-catching.

# Choosing and using accessories

The range of ancillary equipment available for your Zenith (both from the USSR and a multitude of other sources) is so vast that we can only give very brief details here of the when, why and how of choice and use.

**Wide-Angle Lenses** — are available in focal lengths from 16mm to about 35mm, the shorter the focal length the wider the area covered. They are used in any situation that requires greater-than-normal area coverage, e.g., landscapes, interiors, architectural photography etc. In space-inhibiting

*With 28mm lens*

*With 58mm lens*

situations they allow you to retain sufficient of more distant surroundings or background to show relationship to an important close-up subject. Generally a 28mm or 35mm type is found most useful since they're relatively inexpensive, usually have wider maximum apertures, and are less prone to distortion than the shorter focal lengths.

● A feature of wide-angle lenses is their extended 'depth-of-field', useful in landscape work especially but a possible disadvantage when it comes to ascertaining correct focus (e.g. the microprism spot in the Zenith EM viewfinder may not disappear entirely). Focusing is often easier if you first set the lens to its minimum distance setting, then raise the camera to your eye and turn

*With 135mm lens*

the focusing ring as quickly as possible until the image appears sharpest. (If you start with the lens at or close to the correct focusing distance, or hold the camera to your eye for a long time, it will probably be more difficult to distinguish the point of sharpest focus).

**Telephoto Lenses** are available in focal lengths from 85mm (1.5 x magnification compared to standard lens) to about 1000mm. A 135mm lens is generally found to be most useful, certainly for candid photography (children at play, people strolling, street buskers etc), as in most cases you'll find you get a large enough image on the film, and, because you're further away than normal, more pleasing perspective and some beautifully

*With 300mm lens*

relaxed and natural expressions. For longer range work (e.g. stadium sports, animals) a 200mm or even a 300mm lens could be a useful addition.

● Remember that telephotos magnify not only the image but also any camera or subject movement correspondingly, so (a) always use the fastest possible shutter speed (as a general guide a minimum speed roughly equivalent to the lens's focal length — e.g. 1/125th sec for a 135mm lens) and (b) if you're without a tripod try to find ways of bracing yourself to hold the camera extra-steady during exposure (e.g. stand with your body firm against a wall or rest both elbows on the top post of a fence). Wherever you are, try to find a position that gives camera and lens the best possible support; this slight additional effort will pay off in sharper clearer telephoto pictures.

● When using lenses of 200mm focal length or longer there may be some slight "cutting off" effect on the left hand side of the film image but this will probably be masked off by the slide mount or in printing.

**Close Up Photography** comes easy with your Zenith. Many pictures (say of two or three flowers, book or magazine illustrations) can be taken without any accessory at all — just turn the Focusing

Ring [12] of your standard lens to its minimum distance and move your camera towards the subject until the viewfinder image is at its sharpest ... you'll find you can fill the frame with an object around  $6\frac{1}{2}$ " x 10" in area. For smaller subjects you need to get closer by using a *supplementary close-up lens* screwed into the filter mount of your standard lens or *extension tubes* or *bellows unit* inserted between camera and lens.

**Supplementary lenses** are easiest to use since they don't require any increase in exposure — set against this though they do reduce the camera lens's fine resolving power at the edge of the field unless the aperture is stopped well down. They are usually available in powers of 1, 2, or 3 dioptres;

First three pictures show effect of each single tube, fourth picture shows bellows used at maximum setting.

the higher the number the closer you can approach your subject (consult your dealer for the best type to suit your needs).

**Extension tubes** allow photography at even closer range than supplementary lenses. Normally sold in sets of 3 varying lengths, they can be used singly or in any combination to provide a number of fairly definite magnification steps, allowing you to fill the frame with subject sizes from about 2.7" x 4" to as small as  $1\frac{1}{2}$ " x 1" (life size).

**A bellows unit** offers even further advantages since magnification is considerably greater and also continuously variable over a wide range (ideal for really small and even live subjects like insects).

Subjects ranging from about 0.8" x 1.2" to 0.4" x 0.6" (2.5 times life size — or even greater depending on lens in use) will fill the viewfinder frame.

● Since both extension tubes and bellows units make the light rays travel a greater distance as the lens is moved further from the film, they require an increase in exposure over that indicated by a meter reading. The increase required varies proportionately with the degree of extension and the focal length of the lens and can be found from the full data tables usually provided with tubes and bellows. This slight inconvenience in operation over the use of supplementaries is offset by the fact

that optical performance of the camera lens is not affected in any way and that a greater and more varied magnification range is obtainable.

**Photomicrography** – yes, you can even take pictures through a microscope with your Zenith! At moderate magnifications no accessory is needed other than a rigid tripod or copy-stand to hold your camera, complete with lens, over the eye-piece of the microscope. For more professional results and at higher magnifications the camera body should be attached direct to the microscope by means of a 42mm thread mount CA-3 Microscope Adaptor (obtainable through your dealer or direct from Zenith House).

**Lens Hoods** help prevent stray light rays (from outside the picture area) from entering the lens and causing flare due to reflections from internal camera and lens surfaces – they generally improve picture contrast and are certainly essential if pictures are to be taken against any strong light source. Both folding rubber and rigid metal types are available from your dealer and these vary in shape and size according to lens focal length. (NEVER use a hood intended for long focus lens with a shorter focus lens).

**Filters** are discs of coloured glass or gelatine that are used to create special effects or improve rendering or contrast with colour or black and white films. A selection of the most useful types is shown opposite.

● To compensate for the light absorbed by the filter, an increase in exposure is required (except for 1A and UV filters). To obtain this, either (a) determine exposure in normal way, then open up lens the number of f/stops shown, or (b) divide ASA Film Speed by the 'Factor' listed, set the resultant (lower) film speed on your Exposure Meter or Flash Calculator, and then determine and set exposure in the normal way. (Consult film instructions for recommendations for specific film types.)

Filter Type	Appearance	Purpose	Film Types	EXPOSURE INCREASE*	
				f/stops	Factor
1A (Skylight)	Pale Amber	Improves colours outdoors when light is blue.	All	0	1
UV (UV16)	Colourless	Warms colours at high altitudes or when subjects are in shade. Darkens skies with black & white films.	All	0	1
Polarizer	Neutral	Eliminates reflections, glare from water, glass, darkens sky, makes clouds more prominent, improves colour saturation.	All	1½-2	3.0-4.0
81A	Red/yellow	Gives most pronounced 'warming' effect, use on overcast or rainy days.	Colour	½	1.4
82A	Light Blue	Reduces excessive reddishness of day-light in early morning, late evening.	Colour	½	1.5
K2 (Y2)	Yellow	Darkens sky, makes clouds stand out clearly.	B & W	1	2.0
O2 (G)	Orange	More pronounced cloud/sky separation.	B & W	2	4.0
G2 (YG)	Yellow-Green	Lightens trees, grass, foliage; shows flesh tones more clearly where foliage is visible also darkens blue skies.	B & W	1	2.0

Also from the USSR, with a quality to match your Zenith camera . . .

## The Zenith UPA5M Enlarger

- excellent 4-element 50mm f3.5 anastigmat lens
- accurate automatic focusing from 2.5× to 8× magnification
- built-in override control permits manual focusing and allows greater enlargements
- precise 24 × 36mm single-glass negative carrier with slip-in masks for  $\frac{1}{2}$  frame and sub-miniature
- colour drawer holds up to four 6 × 6cm filters
- supplied complete with 75W lamp
- Enlarger folds away completely into the baseboard/ carrying case, measuring only 4 × 14 × 17 inches, weighing only 15lb.

Some other examples of optical excellence from the USSR

## Helios Binoculars

All Helios Binoculars have fine-quality fully-coated optics, easy centre-wheel focusing and adjustable right eyepiece. They are complete with neck-strap and leather carrying case and strap. All are supplied with haze-reducing filters.
